

# **Preserve and Enhance:** *Balancing Goals for the Internet*

**APRICOT**

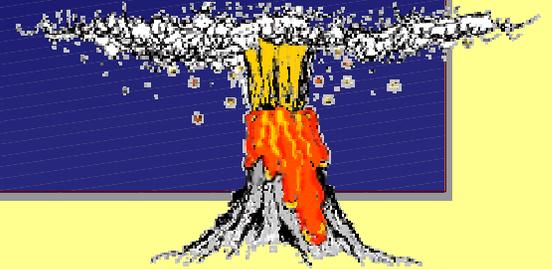

Kuala Lumpur - 2004

**Dave Crocker**

Brandenburg InternetWorking

<<http://brandenburg.com/current.html>>

# Things *Are* Different Today

- ✿ **The Net's operation is more complex and less reliable**
  - ✗ Firewalls, NATs, Routing partitions, Spam, Worms, internationalization (localization), "Governance"
- ✿ **The Net's architecture is reaching serious limits**
  - ✗ Collaboration, Wireless, Mobility, Multihoming, Real-time audio and video, Peer-to-Peer
- ✿ **The Net's technical community is fragmented**
  - ✗ Poor cross-area communications, Long standards cycles, Narrow and complex specifications, political factions

# Lessons: Recent Personal Experiences – I

## ✿ Facsimile

- ✗ Improve service, by copying related, existing service
- ✗ Saves on debate about “needs” and “utility”

## ✿ Instant messaging

- ✗ Needs a QOS that is incompatible with today’s email
- ✗ Difference between “protocol” and “service”

## ✿ Internationalized Domain Names and Spam

- ✗ Local criteria and actions, within global service
- ✗ Technical response to social issues

# Lessons: Recent Personal Experiences – II

- ✿ **Emergency services**
  - ✗ Demand for periodic QOS
  - ✗ Possibility of local structure, without global coordination
- ✿ **Multiaddressing (mobility/multihoming)**
  - ✗ Infrastructure vs. Endpoints
  - ✗ Common core vs. specialized mechanisms
- ✿ **IETF**
  - ✗ Reduced timeliness and productivity
  - ✗ Fragmented, complicated mechanisms
- ✿ **And (*sigh*) ICANN**
  - ✗ Nothing is mundane

# Basics in Scaling: *More and Faster*

*Continue what we have been doing for 35 years*

<b>Bandwidth:</b> Tune performance parameters	<b>56 kbps → 1+ gbps</b>
<b>Networks:</b> Hierarchical and area routing	<b>1 → 140,000+</b>
<b>Hosts and routers:</b> Address space, and maybe namespace	<b>4 → 4 million(?)</b>
<b>Users:</b>	<b>500 → 500 million</b>
<b>User Application Protocols:</b> Not so impressive...	<b>5 → 13</b>

# Threat to End-to-End Model?

- ✿ **End-to-End has never been about “direct” exchanges**
  - ✗ Packet-switching is based on mediation
  - ✗ Inter-networking – AS, OSPF vs. BGP
  - ✗ Email, of course
- ✿ **Mediation is our friend**
  - ✗ Divide-and-conquer makes scaling tractable
  - ✗ Even “peer-to-peer” requires mediation, e.g., rendezvous
- ✿ **These are “*tussle*” boundaries** (*Clark, et al*)
  - ✗ One challenge is that we have more tussles, at more levels
  - ✗ The real challenge is to make designs that *anticipate* boundaries

# End-to-End *Should* Mean...

- ✿ Design a peer-to-peer *model*, if possible
  - ✗ Design for interactions between endpoints
- ✿ Internet model of minimal infrastructure service
  - ✗ Design complexity at the edges
  - ✗ When it becomes popular, it looks like infrastructure
  - ✗ Design for edge *network* versus edge *host*
  - ✗ Infrastructure net vs. edge net vs. edge host *operation*
- ✿ When design must specify new infrastructure
  - ✗ Add it as *adjunct* to endpoints
  - ✗ Add it for special cases, only, if possible

# Multiaddressing

- **Overlapping requirements**

**Mobility:** Different addresses over time

**Multihoming :** Different addresses at the same time

- **Hosts need to add/remove locators dynamically**

- ✘ **And it would be nice to preserve existing connections**

- **Architectural challenges**

- ✘ **Find a destination that is mobile or behind a firewall**

- ✘ **Change the infrastructure versus add to transport or new “wedge” layer?**

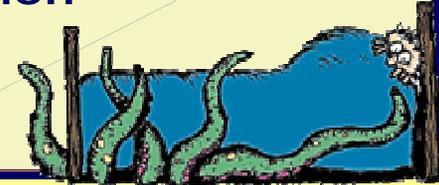

- ✘ **Separate identifiers from locators**

- ✘ **New identifier space versus use existing one?**

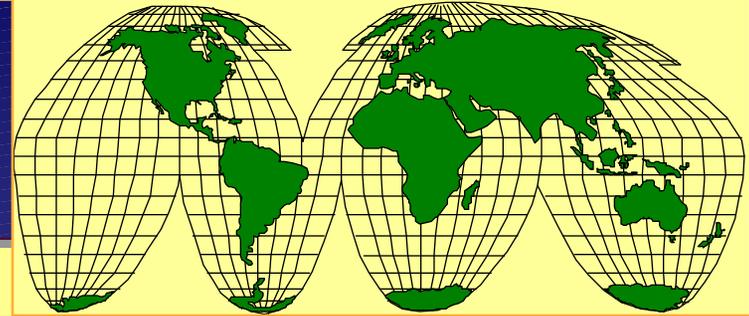

- ✘ **Put Identifier into every payload packet?**

# Spam

- ✿ **Email is more complex than people usually realize**
  - ✗ And having to worry about human factors is distracting
- ✿ **Spam is a social problem**
  - ✗ Technical solutions need to follow the social assessment
  - ✗ Technicians make bad social scientists
  - ✗ Social scientists make bad engineers
- ✿ **Complicated and simplistic solutions will be damaging**
  - ✗ There is no such thing as an “interim” solution

# Observations

- ✿ **New applications propagate *very* slowly**
  - ✗ Modified applications propagate *much* slower
  - ✗ Rate of adoption depends of adoptee incentives
- ✿ **Internet architecture is getting more fragmented**
  - ✗ Uncoordinated, piecemeal designs
  - ✗ Large, cumbersome designs
  - ✗ Failure to incorporate reality of user-driven intermediaries
- ✿ **Scaling issues get little serious attention during design**
  - ✗ Large-scale use
  - ✗ Large-scale administration and operations

# The Balancing Act

- ✿ **Simpler designs**
  - ✗ Long list of “requirements” is for the future
  - ✗ Only a subset needs to be satisfied initially
- ✿ **Much quicker specification cycles**
  - ✗ Permits incremental enhancement, based on experience
- ✿ **More cross-area coordination, sooner**
  - ✗ Applications, operations, security, management

**Terima Kasih**
